New Directions in Cryptography

Invited Paper

WHITFIELD DIFFIE AND MARTIN E. HELLMAN, MEMBER, IEEE

Abstract—Two kinds of contemporary developments in cryptography are examined. Widening applications of teleprocessing have given rise to a need for new types of cryptographic systems, which minimize the need for secure key distribution channels and supply the equivalent of a written signature. This paper suggests ways to solve these currently open problems. It also discusses how the theories of communication and computation are beginning to provide the tools to solve cryptographic problems of long standing.

The best known cryptographic problem is that of privacy: preventing the unauthorized extraction of information from communications over an insecure channel. In order to use cryptography to insure privacy, however, it is currently necessary for the communicating parties to share a key which is known to no one else. This is done by sending the key in advance over some secure channel such as private courier or registered mail. A private conversation between two people with no prior acquaintance is a common occurrence in business, however, and it is unrealistic to expect initial business contacts to be postponed long enough for keys to be transmitted by some physical means. The cost and delay imposed by this key distribution problem is a major barrier to the transfer of business communications to large teleprocessing networks.

Section III proposes two approaches to transmitting

The diagram illustrates the concept of a "crypto war" through a comparison of traditional locks and keys with modern digital key pairs. It features two main sections:

- Top Section:** Shows a "Key pair" (padlock and key) above a box labeled "Private key". An arrow points from this section to a box labeled "Trent" containing a judge's gavel icon.
- Bottom Section:** Shows another "Key pair" (padlock and key) above a box labeled "Shared key". A dashed arrow points from this section to a box containing the Verisign logo and other icons.

Key labels are placed near their respective icons: "Key pair" (above the top padlock), "Private key" (below the bottom padlock), and "Shared key" (below the bottom padlock).

The diagram illustrates the relationship between a "Key pair" (represented by a lock and a key) and a "Private key" (represented by a single key). A dashed arrow points from the "key" label under the Australian PM's photo to the "Key pair" icon. Another dashed arrow points from the "key" label under the "Shared key" icon to the "Private key" icon. To the right, there is a box labeled "Trent" containing a judge's gavel icon, and logos for Verisign, a green robot head, and a red letter "C".

Amber Rudd knows nothing about encryption, says Amber Rudd

Nobody expects Rudd to have a PhD in cryptography but she does need to understand how backdooring encryption would disadvantage perfectly legitimate businesses and potentially cost them dearly.

Speaking at the Conservative Party conference earlier this week the UK home secretary, Amber Rudd, stated that she didn't need to "understand how encryption works to understand how it's helping the criminals." She does, however, need to understand how backdooring encryption would disadvantage perfectly legitimate businesses and potentially cost them dearly.

With such things as the EU General Data Protection Regulation coming into play in May next year, and the UK Data Protection Bill already progressing through Parliament, encryption is a topic that will not be going away. It's vital that businesses not only know under what circumstances encryption should be implemented, but also understand the how such encryption gels with the regulatory compliance process. That Rudd is, in effect, muddying the waters with demands for technical solutions to enable encryption to be broken on demand is unhelpful to say the least.

Amber Rudd - doesn't need to "understand how encryption works to understand how it's helping the criminals."

Private key

Private key uses the same key for encryption and decryption ... how does Bob send the key to Alice?

Diffie-Hellman

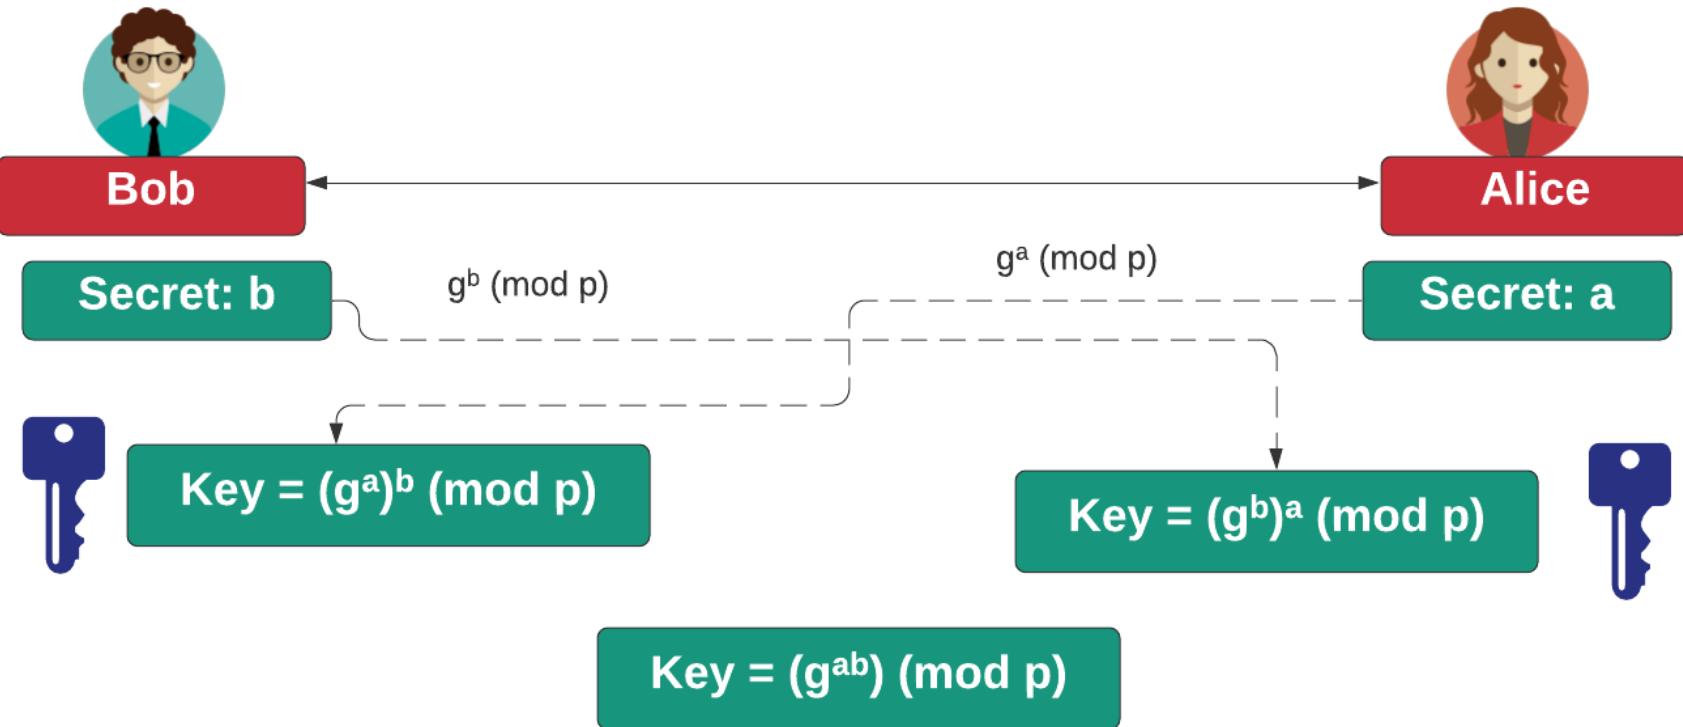

One of the most widely used methods for creating a secret key which is the same for Bob and Alice

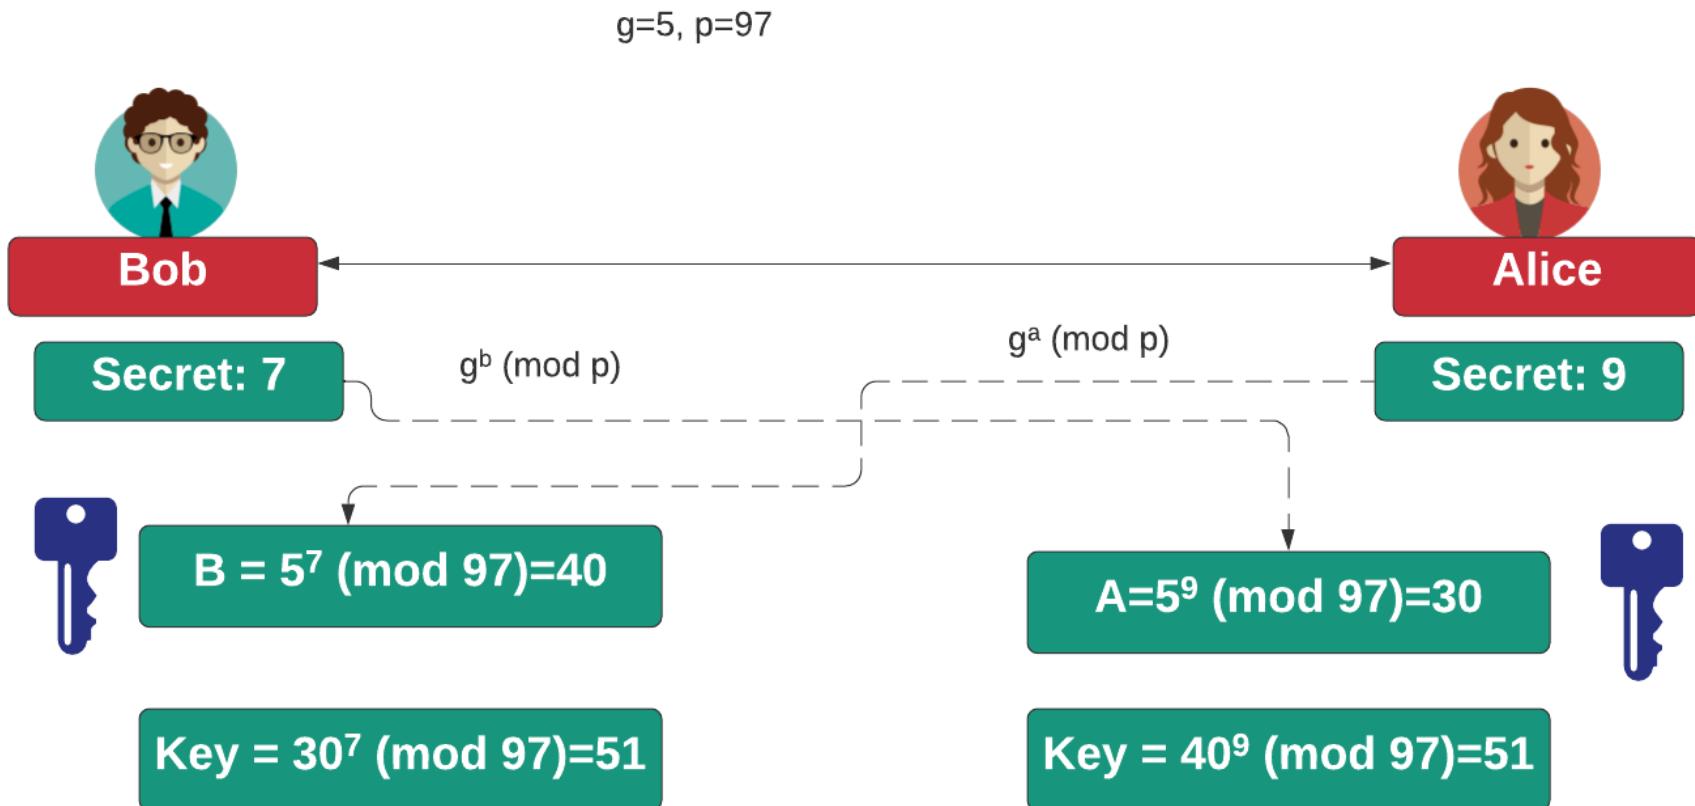

Key Exchange

- **Forward secrecy (FS)**, which means that a comprise of the long-term keys will not compromise any previous session keys. A leakage of the public key of the server would cause all the sessions which used this specific public key to be compromised. FS thus aims to overcome this by making sure that all the sessions keys could not be compromised, even though the long-term key was compromised.
- **Ephemeral**. With some key exchange methods the same key will be generated if the same parameters are used on either side. This can cause problems as an intruder could guess the key, or even where the key was static and never changed. With ephemeral methods, a different key is used for each connection, and, again, the leakage of any long-term would not cause all the associated session keys to be breached.

- In 2015, a paper entitled *Imperfect Forward Secrecy: How Diffie-Hellman Fails in Practice* – showed that it was fairly easy to precompute on values for two popular Diffie-Hellman parameters (and which use the DHE_EXPORT cipher set).
- The research team found that one was used as a default in the around 7% of the Top 1 million web sites and was hard coded into the Apache httpd service. Overall, at the time, it was found that over 3% of Web sites were still using the default.
